

1 Overview

We did a visualization of data using PCA and also a performance evaluation between PCA with RBF and simply RBF. Both their codes can be found in the Github Milestone 4 folder. Our performance evaluation used a 10 time 10-Fold Cross Validation on MSE and R^2 . We then used a sign test to determine which method was better.

2 Building the Model

Feature transformation can be seen in our CV file. We used the exact same feature transformation for both models and evaluated both of them using MSE and R^2 . Our process was feature transformation to PCA to RBF, and feature transformation to RBF. Obviously, we also used the same data sets. Note, RBF was the same as Milestone 1.

For PCA, we visualize the model using histogram models and dependencies for 11 dimensions, using whiten. The variance retained from 11 components is around 96 percent. We wanted to reduce to 2 or 3 dimensions in order to visualize, but when we did that we obtained much worse results - 11 dimesnions proved to be the most accurate. Essentially, we lost too much variance/data by condensing our features into too few dimensions, especially for RBF.

3 Visualization

In order, we have the following images: 1) A figure of a reduction to 2 dimensions. We can see that while there are some discrepancies, there is too much overlap for an RBF to give a proper prediction. 2) A figure of a reduction to 3 dimensions. A little more clarity, but also clear that it is not good enough. 3) A histogram of how often each component shows up. 4) A dependency chart that shows how much each feature from the original impacts each component. 5) A comparison between each component that shows the correlation between them visually.

4 Performance Comparison

Shown in the chart below of MSE and R^2 results of each 10-Fold CV run. PCA had an average MSE of 264.637 and R^2 of 0.9624 while RBF had an average MSE of 266.301 and R^2 of 0.9619

| PCA | RBF | MSE Winner |
|-------------|-------------|------------|
| 266.4561003 | 268.9720765 | PCA |
| 263.2960901 | 268.1444154 | PCA |
| 266.803272 | 265.8051147 | RBF |
| 257.8432446 | 260.9941679 | PCA |
| 266.2363569 | 270.4000389 | PCA |
| 268.7418446 | 263.7731692 | RBF |
| 270.9569755 | 274.6385528 | PCA |
| 268.1189536 | 266.8380138 | RBF |
| 258.9771179 | 261.4804447 | PCA |
| 258.9426846 | 261.9596406 | PCA |

| PCA | RBF | R^2 Winner |
|------------|------------|--------------|
| 0.96195218 | 0.96122566 | RBF |
| 0.96255366 | 0.9611656 | RBF |
| 0.96177291 | 0.96212258 | PCA |
| 0.9642735 | 0.96331164 | RBF |
| 0.96199314 | 0.96068929 | RBF |
| 0.96148387 | 0.96305067 | PCA |
| 0.96069516 | 0.95958824 | RBF |
| 0.96112886 | 0.96171172 | PCA |
| 0.9639274 | 0.96328531 | RBF |
| 0.96409666 | 0.9631571 | RBF |

5 Statistical Sign-Test

We use a non-parametric test because RF and RBF are both non-parametric methods. The null hypothesis for the sign-test is $H_0 : p(RBF_{win} > RF_{win}) = 0.5$.

For sign-test would reject the null hypothesis. For $\alpha = 0.05$ and $n = 10$, we need $RBF_{win} or RF_{win} > 8$. For MSE, PCA only does better 7 times, so we fail to reject the null hypothesis. For R^2 , RBF only does better 7 times, so we also fail to reject the null hypothesis. Thus, with a 95 percent confidence, we fail to reject the null hypothesis.
